A variable gain amplifier includes a voltage divider input stage for receiving a signal to be amplified. A first voltage amplifier is connected in cascade with the voltage divider for amplifying the signal to be amplified. The voltage divider input stage includes a variable impedance circuit having a second voltage amplifier. The second voltage amplifier includes an input and an output. An impedance element is connected between the voltage amplifier input and output. The voltage divider input stage is connected in series to a second impedance element. Each of the voltage amplifiers has its gain controlled by a bias current source.

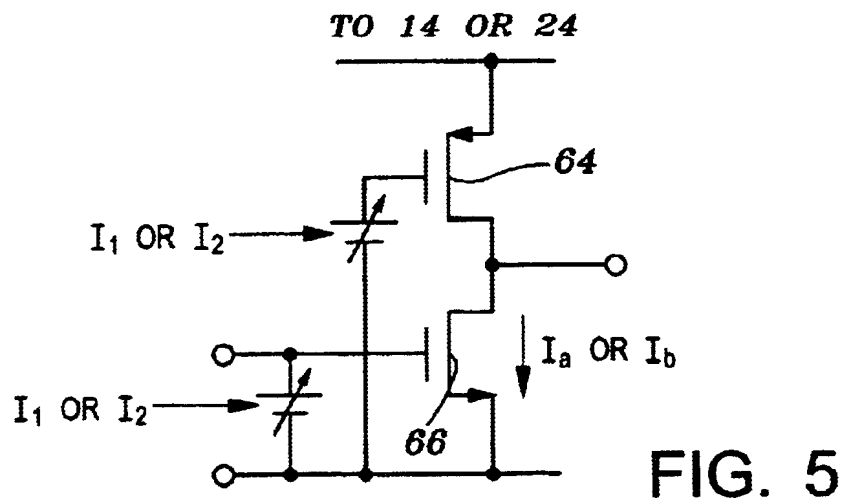

FIG. 5

1

VARIABLE GAIN AMPLIFIER

TECHNICAL FIELD OF THE INVENTION

The present invention relates to variable gain amplifiers, and more particularly to a variable gain amplifier used in communications devices.

BACKGROUND OF THE INVENTION

In a wireless communications environment, a wireless

2

a signal to be amplified. A first voltage amplifier is connected in cascade with the voltage divider for amplifying the signal to be amplified. The voltage divider input stage includes a variable impedance circuit having a second voltage amplifier. The second voltage amplifier includes an input and an output. An impedance element is connected between the voltage amplifier input and output. The voltage divider input stage is connected in series to a second impedance element. Each of the voltage amplifiers has its

3

of the current generated by current source 36 minus the value of the voltage generated by circuit 42 divided by the value of resistor 40. The bias currents I_a and I_b (FIG. 1) are proportional to the currents 11 and 12, respectively.

FIG. 3 illustrates circuitry for an embodiment of voltage feeding circuit 42 and current output circuits 44 and 46 which includes a field effect transistor or bipolar transistor 50 and an operational amplifier 52. A source or an emitter of transistor 50 and the negative input of operational amplifier 52 are connected to the node N_1 or node N_2 . An output of operational amplifier 52 is connected to a gate or base of transistor 50. A positive input of the amplifier 52 is fed with a positive or negative half of the control voltage. The output current I_1 or I_2 is generated from the drain or collector of transistor 50.

Resistor 40 (FIG. 2) is compensated for temperature and process variations. As illustrated in FIG. 4, a compensation circuit includes a resistor 56 and a constant current source 58 and an estimating circuit 60. Resistor 56 is disposed in the same environment and structure of resistor 40 and is fed with a current from current source 58. The estimating circuit 60 measures resistance fluctuation of resistor 56 by comparing a voltage drop across resistor 56 with a standard value, and compensates resistor 40 accordingly. Current source 58 generates a current whose temperature coefficient has the same absolute value, but the opposite sign of the temperature coefficient of resistor 40.

FIGS. 5, 6, and 7 illustrate various components which may be utilized in amplifiers 14 and 24. Each load of the amplifier elements in each amplifier 14 or 24 is an active load including transistors 64 and 66 (FIG. 5). The currents I_a and I_b generate a bias voltage for the active load represented by transistors 64 and 66.

FIG. 6 illustrates amplifiers 14 and 24 having a bias circuit 70, a differential pair of two or more transistors 72, a transistor 74 which provides a constant current source and which provides a bias current for the differential pair 72 and impedance elements 78 and 80, and loads 82 and 84 for differential pair 72. Transistors 72 and 74 may comprise, for example, field effect transistors or a bipolar transistor. Impedance elements 78 and 80 are connected respectively between a positive input and a negative output and between a negative input and a positive output of the differential pair 72. Bias circuit 70 converts the current generated by current output circuits 44 and 46 to bias voltages and feeds this bias voltage to gate or bases of the transistor 74 for constant current and active loads.

FIG. 7 illustrates an embodiment of circuitry for amplifier 24 having active loads in which impedance elements 78 and 80 are connected to field effect transistors or bipolar transistors 90 and 92, and 94 and 96, respectively, in order to flow constant current through impedance elements 78 and 80.

Other alteration and modification of the invention will likewise become apparent to those of ordinary skill in the art upon reading the present disclosure, and it is intended that the scope of the invention disclosed herein be limited only by the broadest interpretation of the appended claims to which the inventor is legally entitled.

I claim:

1. A variable gain amplifier comprising:

a voltage divider input stage for receiving a signal to be amplified;

a first voltage amplifier connected in cascade with said voltage divider input stage for amplifying said signal to be amplified;

said voltage divider input stage including a variable impedance circuit having a second voltage amplifier,

4

said second voltage amplifier having an input and an output, and a first impedance element connected between said second voltage amplifier input and output; said voltage divider input stage connected in series to a second impedance element; and

each of said voltage amplifiers having a gain controlled by a bias current source.

2. The variable gain amplifier of claim 1 wherein said amplifiers each include field effect transistors.

3. The variable gain amplifier of claim 1 wherein said bias current sources each include:

first and second current sources;

a variable resistor connected between said first and second current sources;

a voltage feeding circuit connected to said variable resistor for applying a constant voltage; and

first and second current output circuits for generating first and second output currents.

4. The variable gain amplifier of claim 3 wherein said voltage feeding circuit includes an operational amplifier connected to a field effect transistor.

5. The variable gain amplifier of claim 3 wherein said voltage feeding circuit includes an operational amplifier connected to a bipolar transistor.

6. The variable gain amplifier of claim 3 wherein said current output circuits each include an operational amplifier connected to a field effect transistor.

7. The variable gain amplifier of claim 3 wherein said current output circuits each include an operational amplifier connected to a bipolar transistor.

8. The variable gain amplifier of claim 3 wherein said variable resistor includes a temperature and process variation compensation circuit.

9. The variable gain amplifier of claim 8 wherein said compensation circuit includes a constant current source in series with a resistor and an estimating circuit connected to said resistor for measuring resistance fluctuations of said resistor by comparing a voltage drop across said resistor with a reference value.

10. The variable gain amplifier of claim 9 wherein said compensation circuit constant current source generates a current having a temperature coefficient having an absolute value but opposite in sign as a temperature coefficient of said resistor.

11. The variable gain amplifier of claim 3 wherein said bias current applied to said first and second amplifiers is proportional to said first and second output currents generated by said first and second current output circuits, respectively.

12. The variable gain amplifier of claim 1 wherein said first and second amplifiers each include a load having a transistor such that said bias current sources create a bias voltage for said load.

13. The variable gain amplifier of claim 12 wherein each load includes a differential pair of transistors.

14. The variable gain amplifier of claim 1 wherein said first and second amplifiers each include a differential pair of transistors, a constant current source for providing a bias current for said differential pair of transistors and an impedance element as a load for said differential pair of transistors.

15. The variable gain amplifier of claim 14 wherein said first amplifier includes active loads.

16. The variable gain amplifier of claim 1 wherein said impedance element includes an impedance element from a preceding circuit.
